The size and structure of the future population is based on assumptions made for future fertility, mortality, and migration. The calculations are based on observations over the last nine years and an assumption that these trends will continue in the future. The calculations do not take into account municipalities' planned housing construction, company establishment or other future goals and conditions.

The regional population projections are in line with the national projection. A consequence of this is that the sum of the natural increase (the difference between the number of births and deaths), net internal migration (the difference between the number of arrivals and departures within the country) and net external migration (the difference between the number of immigrants and emigrants) is not the same as the population change between two years. The population increase in the tables is calculated as the difference in the size of the population of two given years.

All calculations in the projection models are made with decimal numbers. The calculated results are rounded to four decimal places, based on which our final result file is created. In the table, there are many cells that contain small numbers. By keeping four decimal places, the summation can be done to a large extent. Nevertheless, small differences between the size of the population in a county and the sum of the population of all municipalities in that county might still exist due to the application of rounding.

Both minor and major structural changes in society affect the development of the future population, which means that uncertainty is inherent in the projection. Please note that a population projection is only an estimate of what a future population might look like. Furthermore, uncertainty in the projection generally increases over the years.
