Description

Life expectancy at age 30, by educational attainment (four groups shown). Calculated for 7-year periods.

Life expectancy is the age a person is expected to live to according to current mortality rates. Life expectancy is calculated using age dependent probabilities of death. Mortality rates will most likely change with time. If current positive trends in medicine and other areas effecting survival continue, then current newborns will most likely live longer than what is predicted here.

Two measures are available. Use the Measures menu to select:

1. Expected life years = Expected age at death, calculated as an average over a 7-year period.
2. Ratio (Norway = 100) = Ratio between the county's value and the national value for a given year. Examples; ratio = 130 means that the county's value is 30% higher than the national level. A ratio of 87 means that the county's value is 13% lower than the national level.

Four levels of education are available. Use the Education menu to select:

- All educational levels
- Compulsory education = all who have completed primary and lower secondary school.
- Upper secondary school or beyond = all who have completed an education beyond the compulsory.
- Upper secondary school = all who have completed this.
- Tertiary education = all who have completed an education beyond upper secondary school.

Rationale for indicator

Life expectancy provides information about the health of the population. At national and county level, this is a stable and reliable indicator providing information about changes over time and about differences between population groups.

Over the last 30 years, the health of all groups in Norway has improved, but the improvement in health was greatest for individuals with long education and high income. For example, this group has a higher life expectancy than persons with shorter education and lower income. Within the last decade especially, inequalities in health (physical and mental) have increased for both children and adults. Reducing social inequalities in health is a key objective in public health efforts.

Source

Statistics Norway

Collection

The statistics are based on data in Statistics Norway's population statistics.

Life expectancy was determined by means of a mortality table. From this, the mortality rates were used for a five-year age interval, with two exceptions: The youngest group is divided into 0 years and 1-4 years, and the oldest groups are merged into 85 years and over (85+). In order to obtain sufficiently large figures for the calculations, the mortality table is based on mortality over seven-year periods. Life expectancy is not calculated in instances where the length of the period (7 years) multiplied by the average annual population count is less than 5,000.

Interpretation and sources of error

Uoppgitt utdanning er inkludert i utdanning samlet.

When numbers are missing

Life expectancy is not calculated if the period length (7 years) multiplied by the average yearly population is less than 5000.

Time periods

1990-1996 to 2015-2021 (i.e. calculated for 7-year periods)
